ever, FBG (Fasting Blood Glucose) was found to be a significant determinant factor to proteinuria in Korean obese population. Further larger plausible interventional studies toward the obese population without or with diabetes would be investigated in the near future.

Introduction: The role of low antioxidant capacity in pathogenesis of civilization diseases has been much discussed. The aim of this study was to investigate whether a diet rich in broccoli affects the antioxidant capacity of human blood.

Methods: A randomized study was conducted in a group of ten patients; mean aged 60 years (from 49 to 71 years) with mean of BMI 31.0 kg/m² ± 6.1 suffering from ischemic heart disease (IHD). The nutritional value of the daily diet (antioxidants vitamins, total fat, saturated and polyunsaturated fatty acids supply), was controlled during the whole intervention by 24 hour recall. All subjects received broccoli (lyophilized, equivalent of 20 g fresh vegetable) per day (polyphenols: 89.8 ± 8.2 mg/g, isoflavonoids: 22.8 ± 1.1 mg/g, fresh mass for 6 weeks. Lipids profile (total cholesterol, HDL-cholesterol, LDL-cholesterol, triglycerides), plasma concentration of substances reacting with thiobarbituric acid (TBARS), Total Antioxidants Status (TAS) and erythrocyte glutathione-S-transferase activity (GST) before and after dietary intervention were estimated.

Results: The six weeks of broccoli administration resulted in significant TBARS decrease (from 3.03 to 1.98 mmol/L; P < 0.05), TAS increase (0.68-0.72 mmol/L; P < 0.05) and GST increase (from 1.59 to 2.74 U/g Hb; P < 0.05).

Conclusion: In conclusion the consumption of broccoli can significantly increase the plasma antioxidant capacity however additional studies need to address the complex issues of IHD risk factors (including antioxidant capacity of diets) on cardiovascular health outcomes using a prospective cohort study.

General and obesity nutritional knowledge in health and non-health higher students
Almeida-de-Souza J1 and Veiga-Branco MA2
Polytechnic Institute of Braganza – Health Higher School, 1Diagnostic and Therapeutic Technology Department – Dietetic Scientific Area; 2Social and Behavior Sciences Department

Introduction: Increase nutritional knowledge (NK) is an effective strategy to promote healthy eating practices, preventing and treating obesity. The nutrition education programs should be precede by a NK evaluation, allowing adapting the program to the target population. So, it is important to study the General and Obesity NK in Health (HS) and non-Health Higher Students (NHS).

Methods: Seven hundred and sixty one Portuguese higher students (40.9% HS; 59.1% NHS) completed the NK questionnaire, developed by Parmenter e Wardle (1999), translated and validated (Cronbach’s alpha = 0.914) to sample. Students were categorized into quartiles regarding NK questionnaire score and in two groups referring obesity: the most student (Group1:212,27.9%) didn’t correlate fat intake-obesity; but, in percentage, more HS(106,34.1%) referred obesity as a health problem connected to fat intake than NHS(105,23.6%) and it was statistically significant (Chi-Squared = 123.8, P ≤ 0.001). About the obesity NK, the mostly student (Group1:212,27.9%) didn’t correlate fat intake-obesity; but, in percentage, more HS(106,34.1%) referred obesity as a health problem connected to fat intake than NHS(105,23.6%) and it was statistically significant (Chi-Squared = 104 12, P = 0.001).

Conclusion: HS have major general and obesity NK than NHS, reinforcing the adapting nutrition education programs to target population necessity. Improving NK to NHS should be done, before programs for both groups.

Introduction: Eating adequate amounts of essential nutrients, coupled with energy intake in balance with energy expenditure, is essential to maintain health and to prevent or delay the development of obesity or malnutrition.

Methods: This study was designed to measure the impact of an educational program involving a diet therapy and physical exercises in patients with chronic hepatitis C. We selected 44 patients with obesity and chronic hepatitis C and they were included into an educational program. We evaluated body weight, blood pressure, liver enzymes, lipids, insulin resistance (Homeostasis model assessment HOMA-IR). The liver fibrosis was non-invasively assessed using the Forns index; a value <4.2 excludes liver fibrosis and a value >6.9 is a predictor for significant fibrosis. All patients completed at baseline, 6 and 12 month a food frequency questionnaire. Each recording was analyzed in an individual meeting and they received professional advice.

Results: The average age was 56.98 ± 9.34 years. An average weight loss of 3.56 ± 1.32 kg of the initial weight was recorded parallel with decreased in calories consumption (P < 0.05). Triglycerides decreased from 187.22 ± 48.3 to 163.82 ± 46.8 mg/dL (P < 0.05), cholesterol decreased from 245.64 ± 49.98 to 221.68 ± 44.71 mg/dL (P < 0.05), and HDL-cholesterol increased from 48.39 ± 10.21 to 49.99 ± 11.39 mg/dL (P < 0.05), after 12 months. HOMA-IR decreased from 8.42 ± 4.92 to 6.56 ± 6.81 (P < 0.05). Albumin value, aspartaminotransferase, alanaminotransferase decreased but we did not find significant statistically differences. Forns index decreased at 12 months (P = 0.048).

Conclusion: The present study establishes the positive impact of an educational program on the management of obese patients with hepatitis C.

Conflict of interest: None.

Improvement of metabolic profile with a specific diet on metabolic syndrome patients
Gadulian G, Rusu E and Dragomir AD
Nutrition, ‘Carol Davila’ Medicine University, Bucharest, Romania

Introduction: This study was designed to measure the impact of an educational program involving a diet therapy and physical exercises on metabolic syndrome patients.

Methods: A number of 108 patients – 39 male (36.11%) and 79 female (63.89%), with an average age 47.6 ± 8.6 years, obese
