women with dyslipidemia and after the menopause. Methods: Randomized, single-blind, placebo-controlled trial involving 59 women (50.9±7.7 years) and non-smoker (52.6±8.1 years) Brazilian women. They were randomly assigned to receive placebo (18 subjects), fish oil (32 subjects) or fish oil and vitamin E (19 subjects). Serum lipids anti-LDL- receptors (ADL-R), alpha-tocopherol and TBARS were determined at baseline and after 90 days. Results: No statistical differences were observed in serum lipids, ADL-R, alpha-tocopherol and TBARS. Conclusion: Alpha-tocopherol was shown to protect the plasma from lipid oxidation in both groups. Keywords: menopause, estrogen, fish oil, atheroma, lipid peroxidation.

EFFECT OF VITAMIN A, E, C AND OMEGA-3 FATTY ACID SUPPLEMENTATION ON LIPOPEROXIDATION IN STREPTOZOTOCIN INDUCED DIABETIC RATS: INVESTIGATION OF HEART, LIVER AND KIDNEYS

Background: Diabetes is known to induce metabolic disorders leading to oxidant-antioxidant imbalance. It is also reported that the anti-inflammatory -3 fatty acids such as DHA and EPA may reduce the risk of diabetic complications. This study was designed to determine the effect of supplementation with vitamin A, E and C as well as -3 fatty acids on lipid peroxidation in streptozotocin induced diabetic rats. Methods: Streptozotocin-induced diabetic rats were randomly divided into four groups as control, diabetic control, diabetic with vitamin A, E and C supplementation and diabetic with -3 fatty acids supplementation. After four weeks treatment the rats were euthanized and malondialdehyde levels were measured in blood samples, liver and heart homogenate. Results: In diabetic rats malondialdehyde level in plasma, liver and heart was significantly increased (P<0.05). Vitamin A, E and C supplementation caused a significant decrease in plasma, liver and heart malondialdehyde (P<0.05). A significant decrease in heart malondialdehyde (P<0.05) was also observed in -3 fatty acids supplementation. Conclusion: We concluded that supplementation with vitamin A, E and C as well as -3 fatty acids decreased lipid peroxidation in diabetic rats.

NUTRITIONAL HABITS & CARDIOVASCULAR DISEASE

An elevated prevalence of the risk factors associated to the illnesses of the circulatory system, particularly hypercholesterolemia and arterial hypertension, aim for a special attention in its prevention. This way, the composition of the digested food daily can influence the spreading of Cardiovascular Disease (CVD), which has shown association between the risk factors and the things we consume. The present study had an objective to identify the influential factors of social economics and education in the nutritional meals and to the spreading of CVD. There were 254 individuals studied over the age of 18, belonging in a population of the northeastern of Portugal. Experienced and trained professionals collected anthropometry facts and carried out an interview where personal information, from personal and social level and relative face to the normal and daily ingesta habits. The total individuals included 63% are of the female sex and 37% of the male sex, 37% demonstrate excess weight and 23% Obesity. The married couples, 22% demonstrate risk factors of CVD, 23% that live with family, 5% that live alone, 23% of the individuals with a low education level and 61% of the individuals that are found inactive, present risk factors of CVD. This work reflects the lifestyle of the study population and the nutritional habits of the population in study. In conclusion we found that the social economical and educational lifestyles are associated to the presence or absence of risk factors of a cardiovascular disease, influencing the ingesta and the BMI of the individuals.

ADHERENCE TO THE SOUTHERN EUROPEAN ATLANTIC DIET AND OCCURRENCE OF NONNATURAL ACUTE MYOCARDIAL INFARCTION
[1] Lopez, Carlos; Department of Physiology and Epidemiology of the University of Porto Medical School and Public Health Institute of the University of Porto [2] Rodrigues-Amado, Ferreira; Department of Preventive Medicine and Public Health, School of Medicine, University of Coimbra, Portugal

Background: The Atlantic diet has been described as a characteristic diet of the Northern Portugal and Galicia, Spain. We aim to define, for the first time in the literature, an index that represents the Southern European Atlantic diet (SEAD) and to examine the association between adherence to this dietary pattern and the occurrence of nonnatural acute myocardial infarction (AMI). Methods: A population-based case-control study was conducted in Porto, Portugal. Cases were patients aged ≥18 years hospitalized with an incident AMI (n=820), and controls were individuals without AMI selected randomly from the resident population of the hospitals' catchment area (n=2396). A validated food frequency questionnaire was used in face-to-face interviews to assess dietary intake in the previous 12 months. We developed a SEAD adherence index with nine key components: fresh fish excluding cod fish, cod fish, red and white meat, lamb meat and pork, fish products, dairy products, legumes and vegetables, vegetable soup, potatoes, whole grain bread and wine. A score of 0 to 0 was respectively assigned to each food consumed above or below the sex-specific median in the controls. Results: After adjustment for the main confounders, a one-point increment in the SEAD score was associated with a 10% reduced risk of AMI (odds ratio [OR] 0.90; 95% confidence interval [95% CI] 0.85, 0.96). As compared with individuals in the lower quartile of the SEAD index (lower adherence), those in the upper quartile had a 35% lower likelihood of AMI (OR 0.67; 95% CI 0.57, 0.88; p for trend<0.003). A SEAD index calculated with reverse scoring for red meat and pork products and for potatoes led to an even stronger inverse association between the SEAD and AMI (OR for the upper vs. the lower quartile of SEAD index 0.40, 95% CI 0.30, 0.52) for trend<0.001). Conclusions: Adherence to the SEAD was associated with lower risk of nonnatural AMI. SEAD might contribute to the low coronary mortality in Northern Portugal and Galicia.

PERFIL DO ESTADO NUTRICIONAL E RISCO CARDIOVASCULAR DE PACIENTES AMBULATORIAIS
[1] Audre, Plineta; Câmera da Nutrição/GEPE2GNOTIC-UL - Câmera da Nutrição/GEPE2GNOTIC-UL

A transição alimentar consolida a obesidade como um dos principais agravos nutricionais do Brasil, que em conjunto com as doenças cardiovasculares promovem impactar no perfil de morbidade e morte da população. Deriva disso o objetivo deste estudo foi avaliar o estado nutricional e risco cardiovascular de pacientes ambulatoriais. Estudo transversal e analítico conduzido por 105 pacientes ambulatoriais em um ambulatório de nutrição de um hospital público de Maringá (Paraná/Brasil) entre abril/2007 e outubro/2008. Para classificar o estado nutricional foi utilizado o índice de massa corporal (IMC), especializado para adultos (OMS, 1995; 1997) e índice (OPAS, 2003) e o risco cardiovascular...
