Abstract: The prevalence of Metabolic Syndrome (SdM) has been confirmed in different ethnic groups including Latin-American population. There are no previous studies on prevalence of SdM in adolescent population using different criteria. Subjects and Methods: 148 subjects, age 16 to 24, 43.2% women, all Hispanic. The prevalence of SdM was compared previous blood sampling for TG, HDL and glucose levels, anthropometric and blood pressure measuring, using DeFerrari, IDF, Cook, Weiss and Ford criteria. Results: The mean values for glucose were 84.89 mg/dL, CC 75.6 cm, TG 47.91 mg/dL, HDL 69.62 mg/dL, systolic/diastolic 115/73 mmHg. The prevalence of SdM using De Ferrari criteria is 7.4%, 6.8% with IDF, 4.4% with Cook, 6.1% with Weiss and only 1.2 subjects with SdM were reported using Cook criteria. Using more prevalent in the males, except Weiss score. Conclusion: With a prevalence of metabolic syndrome was found in the incidence of SdM when compared with previous studies.

NUTRITIONAL HABITS AND CARDIOVASCULAR DISEASE

S. Capitó, H. Sampaio, V. Ferro Leôros
Polytechnic Institute of Bragança, Bragança, Portugal.

An elevated predominance of the risk factors associated to the illnesses of the circulatory system, particularly hypercholesterolserolaemia and arterial hypertension aim for a special attention to its prevention. This way, the composition of the digested food daily can influence the sprouting of Cardiovascular Disease (CVD), which has shown association between the risk factors and the things we consume. The present study had an objective to identify the influential factors of social economies and education in the nutritional state and in the sprouting of CVD. There were 234 individuals studied over the age of 18, belonging to a population of the northeast of Portugal. Experienced and trained professionals collected anthropology facts and carried out an interview where personal information, from personal and social level and relative facts to the normal and daily inages habits. The total individuals invited 83% are of the female sex, 52% of the males sex. 37% demonstrate excess weight and 23% Obesity. The married couples, 22% demonstrate risk factors of CVD, 25% that live with family, 8% that live alone, 32% of the individuals with a low education level and 41% of the individuals that are found inactive, present risk factors of CVD. This work reflects the lifestyles and the nutritional habits of the population in study. In conclusion we found that the social economical and educational lifestyles are associated to the presence or absence of risk factors of a cardiovascular disease, influencing the insta and the BMI of the individuals.

THE IMPACT OF EXERCISE ON VISCERAL OBESITY AND ENDOTHELIAL DYSFUNCTION AT YOUNG SUBJECTS WITH METABOLIC SYNDROME

Introduction. Metabolic Syndrome (MS), a complex disorder including several factors (abdominal obesity, hypertension, insulin resistance and dyslipidemia), is associated with an increased risk of the subsequent development of cardiovascular events by causing vascular dysfunction. The aim of this study was to examine the impact of two training programs, continuous aerobic exercise (CAE) versus intermittent aerobic exercise (IEA) on body composition, abdominal adiposity and endothelial dysfunction at young subjects with metabolic syndrome. Material and method. The study included 40 male patients with MS, with ages between 18-40yrs, which have been separated into two groups: group A(n=20), who has undertaken 40 minutes of continuous aerobic exercise, 5days/week, at submaximal intensity (75-79%VO2max), and group B(n=20) who has undertaken same type of exercise but daily session was divided in two events of 20 minutes at minimum 3hours interval. The training program, that consisted in stationary cycling, has been monitored by a heart rate monitor (PolarFR200). General indications regarding the diet were set for each patient. Results. After 16 weeks of physical exercises we noticed a significant evolution of investigated parameters at group B comparative with group A. Weight (kg): 9.8±12.3±3.5±11 versus 8.9±12.9±3.5±11; waist circumference (cm): 103.17±98.85±7.7 versus 110±35.14±0.2±13.9; BMI: 33.1±30.8±3.5±0 versus 30.6±30.8±3.5±0; HDL (mg/dL): 40±60±5.4 versus 54±60±5.4; HDL (mg/dL): 74±21 versus 37±6±7.1±5.4; brachial artery flow mediated dilatation (%FMD): 5.9±1.8±0.6±2 versus 5.9±1.6±.1±2.5. Conclusions. The present study establishes the positive effect of intermittent aerobic exercise in treatment of metabolic syndrome at young subjects with MS by the effect on visceral obesity and endothelial dysfunction.

THE RISK FOR TYPE 2 DIABETES MELLITUS IN OVERWEIGHT AND OBES PATIENTS WITH METABOLIC SYNDROME

D.A. Miha, 1 M.I. Prățu, 1 D.O. Dragooșu, 2 A.M.C. Oprală, 2 C. Ionescu-Tîrgoviste 1, Diabetes, Nutrition 2 Metabolic Disease Institute “N. Paulescu”, Bucharest, Romania, Department 1 of Diabetes, Course Hospital Ploiești, Ploiești, Romania, clinical Hospital D. Filicu, Bucharest, Romania

Background and aims: Metabolic Syndrome (MS) is a constellation of risk factors for cardiovascular disease and type 2 diabetes (T2DM). Our study analyses the prevalence and particularities of MS (by new, 2009 definition) in overweight and obese subjects, and their 10 years risk of acquiring T2DM, using a diabetes risk algorithm (the QDScore). Material and methods: the study is cross-sectional, compulsory, 20% overweight (31) and obese (68) out-patients -59 women/41 men, aged between 25 and 79 years old, without T2DM. Results and discussions: 47% of the patients were diagnosed with MS, having significantly higher values for age, waist (p<0.05), triglyceride, fasting glycemia (p<0.001) and lower for HDL cholesterol (p<0.001). The risk score for T2DM was significantly higher in patients with MS (p<0.003), especially in the ones presenting 4 or 5 components comparing to those with only 3 components (p<0.01). Patients with high blood pressure, fasting glycemia &#8805;100 mg/dl and waist &#8805;95 cm (women) or &#8805;102 cm (men) presented statistically greater values of the risk score that the ones with normal blood pressure (p<0.001), with fasting glycemia >100 mg/dl (p<0.003) and, respectively, a waist >88 cm (women) or >102 cm (men) (p<0.001). Conclusions: in overweight and obese
